Smart phone/tablet AR:

Advantages:
+ Smart phone/tablet AR enhances the actual environment by overlapping a layer of virtual information on top of it – we can use contextual data such as location and orientation to provide even richer experience in real time.
+ Since smart phones and tablets are already embedded in our everyday lives, the user will not need any additional equipment for the experience.

Disadvantages:
- Since handheld devices such as smart phones/tablets are usually small, the experience is limited by the screen size of the device. The user can only view the virtual information via the device screen and he/she has to point the device camera at a position or object to view the information.

Best suited applications:
★ Smart phone/tablet AR is well suited for applications that make use of location data/computer vision to provide context based information. A good example would be an application which uses location data to annotate surrounding historically significant/prominent buildings around the user.

360° video:

Advantages:
+ In 360° video, the user can look in all directions at a given point of time in the video; this means the user will have a more immersive experience when compared to traditional video where he/she can only see one direction at a given point of time.

Disadvantages:
- The user is limited by the viewpoint of the camera; he/she can only see what the camera sees and hence the experience is not interactive/exploratory.
- 360° video is monoscopic, this means that it's just a 2D video taken in all directions: the user will not have perception of depth from the video.

Best suited applications:
★ 360° video is ideal for recording videos of special events like sports/celebrations where the action is not limited a single direction but things are happening in multiple directions at the same time.

Google Cardboard:

Advantages:
+ Google Cardboard is stereoscopic, this means that the user will have a perception of depth – the two eyes of the user are shown two different images giving him/her the illusion of seeing the real object in 3D space.
+ Inexpensive: accessible to everyone.

Disadvantages:
- The users will experience discomfort and eye strain due to prolonged use; they might also suffer from disorientation for a short period of time after the experience.
- Very small field of vision: around 90°.

Best suited applications:
★ Cardboard is best suited for applications that require demonstrating ideas/models: for example, in civil engineering or architecture. Another surprising application is in the field of journalism where we can

narrate news stories realistically:

VIVE head mounted display:

Advantages:
+ VIVE can be used in immersive and interactive learning – since the environment that the user experiences is virtual, the user can make mistakes without consequences. This is particularly useful for simulative applications that are used in training such as driving or medicine (surgery).

Disadvantages:
- Since VIVE is wired, this leads to reduced mobility for the user.
- VIVE headset completely blocks the eyes, the user will have no view of real world: this would lead a lot of safety concerns.
- The skills that are learnt using a VR environment are only meant to supplement the actual training; this can be used to acquire basic skills but advanced skills should be learnt in the real world as translating the skills from VR to the real world might be difficult.

Best suited applications:
★ Well suited for simulating training applications that have high stakes in real world such as military.

HoloLens:

Advantages:
+ Hololens superimposes virtual elements (holograms) over the real world environment: the user will be able to navigate real world normally as opposed to VR headsets like VIVE or Oculus Rift where the real world is blocked completely.
+ Increased mobility due to the wireless nature of the device.

Disadvantages:
- Limited field of view: the user will not be able to look at the edges of the display.
- In a situation where the user is frequently switching between looking at a real world object and looking at virtual elements, the repeated change in eye focus might lead to AR nausea.
- Looking at super close virtual elements leads to eye strain and discomfort.

Best suited applications:
★ Since Hololens uses the position of the head to manipulate the cursor, it can be used for applications that are designed for people with disabilities. Also well suited for prototyping applications that are used to model/design products.

CAVE2:

Advantages:
+ Can be used for both 2D and 3D immersive applications with added interactive/collaboration opportunities due to the huge form factor.

Disadvantages:
- Multiple people cannot control the application at the same time in 3D mode.

Best suited applications:
★ 3D modelling/collaborative applications.
